A Data Pre-Processing and Deep Neural Network Approach for Potato Leaf Blight Detection

Dr. Chandra Prakash Patidar Department of Information Technology Institute of Engineering and Technology, DAVV, Indore

Abstract— With machine learning being used in agricultural applications, a new domain of science has emerged which is termed as precision agriculture. It is the amalgamation of data science, analytics, AI and ML technologies for enhancing conventional agricultural practices. This paper addresses the challenge of identifying blight (late and early) based on a machine learning approach. In this approach, the image is first pre-processed to convert from RGB to Grayscale and subsequently denoised. Next the statistical features of the image are computed to train a machine learning models based on a probabilistic approach employing the Bayes Theorem of conditional probability. A penalty factor is included for the training purpose termed as regularization which optimize the weight updated mechanism. The final classification accuracy is computed based on the TP, TN, FP and FN rates which yield a classification accuracy of 97.69%..

Keywords— Potato Leaf Disease (blight), Image Denoising, Feature Extraction, Deep Neural Networks, Classification Accuracy.

I. INTRODUCTION

Machine learning and deep learning based approaches are being extensively used for identification of blight (early and late) in potato crops which happens to be a staple in various regions of the world. To automate the process of blight detection, machine learning and deep learning based approaches have been explored [1]. An effective collection of tools for the early identification of potato leaf blight is provided by machine learning techniques. ML algorithms may be trained to discriminate between healthy and diseased potato leaf classes based on subtle visual signals including [2]:

- Minimalistic need for human intervention.
- Quicker decision making.
- Lesser chances of erroneous decision.

This has led to development of machine learning and deep learning algorithms to be employed in several precision agriculture applications, including detection of crop diseases. The use of data analytics and machine in agriculture is widely defined as precision agriculture. Predicison agriculture and IoT are being explored for various applications [3]

Figure 1 depicts the applications of IoT and precision agriculture which are gaining momentum due to the rapid and mass exodus of large populations towards urban areas leading to shortage of manpower in the agriculture sector [4]. The need for providing food security to increasing populations worldwide is also a serious constrain which has led to the direction of research towards automation in agricultural sector [5].

Precision agriculture can have several pertinent applications such as disease detection, pest detection, identification of the evel of ripeness of crops, sensing and deciding the amount of water and nutrients needed in farms etc [6]. This paper examines the salient features of machine learning based models which can be used for crop disease identification focussing on the potato leaf blight disease [7]. The choice of the crop has the underpinnings in the fact that potato happens to be one of the most significant staple crops worldwide which is adversely affected by the blight disease [8].

Fig.1 Applications of Precision agriculture and IoT [1]

Several machine learning and deep learning algorithms have been employed to correctly identify potato leaf diseases among which the most common happen to be the support vector machine (SVM), Random Forests (RF), Convolutional Neural Networks (CNN) Residual Network (ResNet) etc [9]. A brief summary of noteworthy contribution in the filed in presented in table I..

		used for classifying potato blight with an
		F-Score of 0.84–0.98, 0.79–0.94
		and 6.8-8. respectively
5	Tiwari et al. [14]	Feature extraction followed by
		classification using the Random Forest
		algorithm. Classification Accuracy of
6	Inhal at al [15]	9/% achieved.
0	iqual et al. [15]	by Logistic Pagrossion rendered an
		accuracy of 97.7%
7	Taria et al [16]	Image processing followed by
'	rang et al. [10]	Convolutional Neural Networks used to
		obtain an accuracy of 99%.
8	Akther at al.	Transfer learning through the VGG16
	[17]	deep learning model to obtain an
	-	accuracy of 96.88%.

Based on the analysis of existing research in the filed, it can be observed that the neural network model is particularly good at automatically learning hierarchical representations of image features; this eliminates the requirement for feature extraction that is done by hand. However, completely bypassing the feature extraction part may have its own disadvantages which are [18]:

1. Need to extensively copious datasets to effectively train deep learning models [19].

2. Lessened accuracy of classification due to variations in image texture and background.

3. Possibility of vanishing gradient and overfitting.

Fig.1 A typical healthy image (a) and blighted image (b)

Figures 2(a) and 2(b) depict the typical normal and blight infested images. As a machine learning based approach for potato crop blight detection method would necessitate capturing images through unmanned aerial vehicles (UAVs), which results in noise and degradation effects in the image data captured, hence the proposed approach tries to incorporate image denoising (to filter out noise effects), feature extraction and subsequent classification using a deep neural network model. Each of the aforesaid concepts are presented in detail next.

II. EXISTING MODELS

The proposed methodology consists of 3 major parts:

- Image Pre-Processing
- Image Feature Extraction
- Classification

Pre-Processing: The pre-processing parts consists of the RGB to Grayscale conversion as well as denoising the image using the DWT. The mathematical analysis is presented here [20]: For the images, convert RGB to Grayscale using the following relation:

$$Iy = 0.333fr + 0.5fg + 0.1666fb$$
(1)
Where,

Fr, Fg and Fb are the intensity of R, G and B component respectively and

Iy is the intensity of equivalent gray level image of RGB image.

The benefit of this process is the fact that it converts the function of 3 variables to one variable and renders homogeneity.

The next step is the denoising of the image based on the DWT process which tries to filter out the image in the transform domain using wavelet decomposition. The approximate low frequency components are used to retain the actual information while the detailed high frequency components are discarded to remove noise effects [21].

Feature Extraction: The feature extraction process is necessary to compute important statistical features of the images for the final classification process. The features computed in this work are energy, mean, median, standard deviation, variance, entropy, skewness, kurtosis, contrast, correlation, homogeneity, smoothness and rms value. These feature are then then demarcated for the target variable. In order to overcome the difficulties associated with picture classification, the computation of image statistical features is essential. These features are vital for creating precise and dependable classification models because they capture important traits, improve discriminative power, guarantee robustness, and allow efficiency and interpretability. To fully realise the potential of picture-based classification systems, advanced feature extraction techniques must be included as we navigate the ever-expanding field of image analysis [23].

Final Classification: The final classification is based on the design of the deep neural network model which classifies the image as:

- A) Healthy
- B) Blight (early) or blight (late)

For this purpose, the computed and fed to the deep neural network. The image statistical features are measurable attributes that are taken from images and represent different facets of its texture, spatial relationships, and pixel intensity distribution [24]. These characteristics enable efficient differentiation between several groups or categories by offering insightful information about the underlying patterns and structures inside images. mage statistical traits provide resilience against changes in lighting, noise, and geometric alterations. Higher-level properties that are more resistant to

IJERTV13IS090032

distortions are encoded via statistical features, in contrast to raw pixel values, which are susceptible to such alterations [25].

Classifiers generate succinct yet useful representations of visual content by computing statistical parameters including mean, variance, skewness, and kurtosis. These characteristics strengthen the discriminative ability of classification models by encapsulating important statistical characteristics that separate one class from another. As there is no clear demarcation among the normal and blighted potato leaf images, hence a probabilistic classifier is design and used for the final classification based on the Bayes Rule [26]: The weights of the network are updated such that the condition for maximization is satisfied of a new sample bearing a conditional probability defined as:

$$P\left(\frac{X}{X_{i,k_1,k_2,M}}\right) = \frac{P\left(\frac{X_i}{X,k_2,M}\right)P\left(\frac{X_i}{k_1,M}\right)}{P\left(\frac{X}{k_1,k_2,M}\right)}$$
(2)

Here,

P denotes the probability of occurrence of an event.

 X_i denotes the vector corresponding to the bias and weight values of the network.

X denotes the training data set

The essence of the algorithm happens to be the factor termed as penalty $\rho = \frac{\mu}{\nu}$ which controls the movement of the weight vector based on the modified cost function for the network (as a function of weights) given by [27]:

$$F(w) = \mu w^{T} w + v \left[\frac{1}{n} \sum_{i=1}^{n} (p_{i} - a_{i})^{2}\right]$$
(3)

Two major conditions arise in this case:

If $(\pi \ll v)$: in case the errors exhibit a low magnitude.

else if $(\pi \ge v)$: in case the error exhibit a higher magnitude.

Figure 3 depicts the flowchart of the proposed approach. The first step is collecting the annotated dataset with three categories of images. The three categories would be the normal, early and late blight stages. The next process would be the image filtration process to remove effects of noise and disturbance through the discrete wavelet transform (DWT) defined as [28]:

$$W\Phi (Jo, k) = \frac{1}{\sqrt{M}} \sum_{n} X(n) \cdot \Phi(n)_{jo'k}$$
(4)

Here,

W represents the variable in the transform domain J is the scaling factor K is the shifting factor. X is the original raw sampled dataset

 Φ is the kernel of the transform

The DWT can be visualized as a filter/seive which can be used iteratively for data filtering through iterative decomposition of the data, by retaining C_A and remvoing C_D values, and acts as an effective image filter.

The subsequent step is computing the images features (statistical attributes). Subsequently, the features for the dataset are to be annotated as [29]:

$$F_{tar} = [F_N, F_E, F_L] \tag{5}$$

Here,

 F_{tar} denotes the overall feature vector.

 F_N denotes features of normal class.

 F_E denotes features of early blight class.

 F_L denotes features of late blight class.

Next, the features are to be applied to the Deep Neural Network for classification. The network is trained based on the Regularization based Bayes Model with the penalty factor. The probabilistic classification is done as:

For N samples in a set 'U', the probability for a sample to belong to a category can be given by [30]:

$$P(\frac{x}{c_1}), P(\frac{x}{c_2}), \dots, P(\frac{x}{c_n}).$$

Here,

X denotes the new random testing sample.

 $C_1 \dots C_n$, denotes the classes

P denotes probability.

The decision is based on finding the maxima among:

$$P(\frac{x}{C_{1}})$$

$$P(\frac{x}{C_{2}})$$

$$P(max) = \begin{array}{c} \vdots \\ \vdots \\ \vdots \\ P(\frac{x}{C_{2}}) \end{array}$$
(6)

Fig.3. Flowchart of Proposed System

Cn The maximum probability of any category would result in the decision being in the favour of the particular category.:

 $P_{max} = X$

$$P\left(\frac{x}{U}\right) = P\frac{x}{\prod_{i=1}^{i=n}U_i} \tag{8}$$

(7)

Here,

Where,

 $\prod_{i=1}^{i=n} U_i$ cumulative overall probability.

The back propagation based training rule for the network is given by [31]:

$$w_{k+1} = w_k - \alpha \frac{\partial E}{\partial w} \tag{9}$$

Here,

 $w_k \& w_{k+1}$ denote the weights of the present and subsequent iterations.

 α denotes the learning rate.

e denotes the error in the present iterations.

E denotes the error vector.

Based on the classifications of the network for the testing phase, the classification accuracy can be calculated as:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN}$$
(10)

Here,

TP represents true positive **TN** represents true negative **FP** represents false positive

FN represents false negative

The next section presents the results associated with the proposed approach.

III. EXPERIMENTAL RESULTS

This

The experiment has been performed on MATLAB 2020a on a PC with 16BG RAM and Intel i7 processor, coupled with an NVIDIA GTX GPU unit. The results obtained are resented in this section sequentially. The data has been fetched from:

data.mendeley.com/datasets.

The data is annotated in three categories i.e. normal, early and late blight. The 70:30 splitting ratio has been adopted in this case as the generic rule. The subsequent figures depict the step by step process.

Fig.4. Original Test Image

Figure 4 depicts an image for analysis. The subsequent step is the histogram analysis of the images.

Fig.5. Wavelet Analysis of Image (3rd Level)

Fig.6.Histogram and Cumulative Histogram of Original Image at 3rd level

IJERTV13IS090032

Fig.7. Histogram and Cumulative Histogram of Approximations (3rd Level)

Fig.8. Histogram and Cumulative Histogram of Details at Level 3 of Haarlet

Figures 5, 6, 7 and 8 depict the DWT decomposition of the original image followed by the histogram analysis of the original image, the approximate co-efficients and detailed co-efficients respectively.

Table II. Tabulation of data statistical values for original image 'I'

S.No.	Parameters	Values				
1	Maximum	254.4				
2	Minimum	1.47				
3	Mean	152.2				
4	Median	134.8				
5	Standard Deviation	64.17				
6	Medium Absolute Deviation	55.92				
7	L1 Norm	9.97 x 10 ⁶				
8	L2 Norm	4.23 x 10 ⁴				

Table II depicts the statistical DWT features of the original image. A similar analysis can be done for the approximate and detailed co-efficient values.. The observation which can be made is the fact that the values for the original image are closer to the approximations while completely different from the details. This clearly indicates the statistical dissimilarity of the details w.r.t. the original image, and hence can be considered as exogenous noise effects which can be filtered through the DWT approach. The same inference can be drawn from the respective graphical histograms.

The next phase is the feature extraction which is computing the statistical features of the de-noised image which are energy, entropy, mean, median, variance, standard deviation, skewness, kurtosis, inverse difference, homogeneity, correlation and contrast. The features of the annotated image set is computed and the values are depicted in figure 9.

Figure 9 depicts the feature extraction phase of the network, with the annotated feature vectors used to train the network. The total number of images for the classification purpose have been considered as 130 out of the 430 images, whose 300 images are used for training.

Fig.10. Training Parameters

Figure 10 depicts the training parameters of the network which are the Bayes Network parameters such as the training gradient $\frac{\partial e}{\partial w}$, the combination co-efficient $\mu = w_{k+1} - w_k$, changing parameters, sum square parameters and the validation checks to convergence. It can be observed that the model attains convergence at 15 iterations without any validation fail event.

Fig.11. Confusion Matrix

The confusion matrix is generated after the network is tested for the new cases of the samples used for testing for true and false classed. The networks confusion matrix can be used to compute the systems classification accuracy as:

$$Accuracy = \frac{64+63}{64+63+1+2} = 97.69\%$$

The accuracy of the proposed approach is thus 97.69% for the proposed approach.

A summary of the results is presented next:

Table III
Summary of Experimental Results

		Bayesian Regularization
7	Accuracy:	94.2%
	Bonik et al., 2023 [10]	
8	Accuracy:	94.07%
	Singh et al., 2022 [11]	
9	Accuracy:	95.9%
	A.K. Singh et al., 2022	
	[12]	
10	Accuracy	97.69%
	(Proposed Work)	

Table III summarizes the results obtained from the implementation of the proposed approach. A comparison with existing work also shows that the proposed approach outperforms the exiting work in the domain in terms of classification accuracy. The feature extraction phase allows to control the features or attributes based on which the neural network model would further classify the images rather than being dependent on conventional architectures. This allows much more flexibility compared to baseline approaches.

IV. CONCLUSION

In conclusion, it can be said that the potato plant (especially the leaf) is prone to blight disease. If left untreated, potato leaf blight, which is brought on by fungi like Phytophthora infestans, can seriously harm potato crops all over the world and result in large yield losses. Agronomists' subjective and time-consuming visual inspection is the foundation of traditional disease detection techniques. However, there is a chance to completely transform the identification and treatment of potato leaf blight with the introduction of machine learning (ML) and deep learning (DL) approaches. This paper presents not only a machine learning based approach, but rather integrates it with image denoising and statistical feature extraction to train a deep neural network which attains a classification accuracy of 97.69%. The Back Propagation with Bayesian Regularization has been designed to train the probabilistic neural network model with annotated statistical features ..
