A Quantitative Investigation Of Software Metrics Threshold Values At Acceptable Risk Level

Sarabjit Kaur Assistant Professor Dept. of CSE RIEIT, Railmajra. Satwinder Singh Assistant Professor, Dept. of CSE, B.B.S.B.E.C, Fatehgarh Sahib Harshpreet Kaur Assistant Professor, Dept. of CSE, RIEIT, Railmajra.

Abstract

Object-Oriented metrics are more beneficial for the software engineers. Object-oriented design and development is becoming very popular in software development environment. Object oriented development requires not only a different approach to design and implementation, it requires a different approach to software metrics. In the current paper, we use logistic regression to investigate the threshold values against the bad smell for the Chidamber and Kemerer(CK) metrics at five different levels. Two versions of ifreechart were used as a dataset to validate the study. Only the significantly associated metrics were considered for finding the threshold values. The results indicate that the CK metrics have threshold effects at various risk levels and some metrics have useful threshold value at different levels to identify the bad smell.

Keywords

Object-oriented metrics, Threshold values, Risk levels, open source software.

I. INTRODUCTION

Software quality has been a major challenge in various software projects since years. The quality of software can be evaluated using different types of software metrics. Although it has always been the major concern in software development but still lacks the outline of standards which can measure it [4]. As quality is effected by maintainability, in order to

achieve it one needs to know what characteristics of a product actually affects it. In their work, has emphasized the factors that decrease maintenance effort. These are use of structured techniques, Use of modern software, Use of automated tools, Use of data-base techniques, Good administration, and experienced maintainers. Modification of a software product after delivery to correct faults, to improve performance or other attributes, or to adapt the product to a modified environment. Basically, this means that any activity that modifies software product after its release is software maintenance. Adaptive maintenance is the modification of a software product performed after delivery to keep a computer program usable in a changed or changing environment. Corrective maintenance is the reactive modification of a software product performed after delivery to correct discovered faults. Perfective maintenance is the modification of a software product after delivery to improve performance or maintainability [11]. Fowler and Beck have informally described bad smells in code as bad or inconsistent parts of the design of an Object-oriented System. Flower has identified 22 code smells and associated each of them with the refactoring transformations that may be applied to improve the structure of code [7]. Refactoring increases the code maintainability. readability and Refactoring applied at any level depends on the type of design defect found in the

system and has a direct influence on the software maintenance cost [10].

The process of refactoring is applied in three different stages which identification of problematic area, choice of appropriate refactoring technique and application of refactoring techniques. The object-oriented software metrics were investigated and the most suitable metrics is evaluated. The metrics were selected on the basis of their ability to predict different aspects of object-oriented design. Then, tool was used to measure the metric quality. An adequate result means the code base must consist of both well and badly systems designed [2]. The regression is used to investigate the threshold effects of the CK metrics suite, and then validate the thresholds to identify faulty classes. This model is used to find the threshold effects in Eclipse 2.0. [9]. In this research, the aim is to find the threshold values of object oriented metrics based on the bad smell. Then the validation of these metrics threshold values will be done. Only the significantly associated metrics were considered for finding the threshold values. The need is to find the threshold values of metrics using bad smell successfully and then validate this threshold values will be done.

2. LITERATURE REVIEW

In this section, we review the previous works that are related to the validation and effects Object-Oriented threshold of metrics. Shatnawi R[13]. In this paper, we use a statistical model, derived from the logistic regression, to identify threshold values for the Chidamber and Kemerer (CK) metrics. The methodology is validated empirically on a large opensource system—the Eclipse project. The empirical results indicate that the CK metrics have threshold effects at various risk levels and validated the use of these thresholds on the next release of the **Eclipse** project—Version 2.1—using decision trees. In addition, the selected

threshold values were more accurate than those were selected based on either intuitive perspectives or distribution parameters. Shatnawi [9]. Bad smells are used as a means to identify problematic classes in object-oriented systems for refactoring. Although there is a plethora of empirical studies linking software metrics to errors and error proneness of classes in object-oriented systems, the link between the bad smells and class error probability in the evolution object-oriented systems after the systems are released has not been explored. There has been no empirical evidence linking the bad smells with class error probability so far. This paper presents the results from an empirical study that investigated the relationship between the bad smells and class error probability in three error-severity levels in an industrial-strength open source system. The research, which was conducted in the of the post-release context system evolution process, showed that some bad smells were positively associated with the class error probability in the three errorseverity levels. This finding supports the use of bad smells as a systematic method to identify and refactor problematic classes in this specific context. Rosenberg[8] Object oriented technology uses objects and not algorithms as its fundamental building blocks, the approach to software metrics for object oriented programs must be different from the standard metrics set. Some metrics, such as lines of code and cyclomatic complexity, have become accepted as "standard" for traditional functional/ procedural programs, but for object oriented, there are many proposed object oriented metrics in the literature. The question is, "Which object oriented metrics should a project use, and can any of the traditional metrics be adapted to the object oriented environment?" Basili et al.[21]. This paper presents the results of a study in which we empirically investigated the suite of object-oriented (OO) design metrics introduced. More specifically, our

goal is to assess these metrics as predictors of fault-prone classes and, therefore, determine whether they can be used as early quality indicators. This study is complementary to the work described where the same suite of metrics had been used to assess frequencies of maintenance changes to classes. To perform our validation accurately, we collected data on the development of eight medium-sized information management systems based on identical requirements. All eight projects were developed using a sequential life model. well-known cvcle a 00 analysis/design method and the C++programming language. Based empirical and quantitative analysis, the advantages and drawbacks of these OO metrics discussed. are Several Chidamber and Kemerer's OO metrics appear to be useful to predict class faultproneness during the early phases of the life-cycle. Also, on the data set, they are better predictors than "traditional" code metrics, which can only be collected at a later phase of the software development processes. Bender[16] In this paper a method for quantitative risk assessment in epidemiological studies investigating threshold effects is proposed. The simple logistic regression model is used to describe the association between a binary response variable and a continuous risk factor. By defining acceptable levels for the absolute risk and the risk gradient the corresponding benchmark values of the risk factor can be calculated by means of nonlinear functions of the logistic regression coefficients. Standard errors and confidence intervals of the benchmark values are derived by means of the multivariate delta method. The proposed approach is compared with the threshold of ULM (1991) model for assessing threshold values in epidemiological studies. Gyimothy et al. found significant association between some of the CK metrics and the fault-proneness of classes, expect the **NOC** metrics.[19] for Rosenberg suggested a set of threshold

values for the CK metrics that can be used select classes for inspection redesign[8]. Bender [16] pointed out that the estimated threshold values should only be considered suitable if the assumption of the regression model, (i.e., a constant risk below the threshold) is plausible. Bender redefined the threshold effects as acceptable risk level. Thus far, there is no consensus on the threshold values for software metrics, and perhaps not even for what are the best methods to use in the search for the threshold effects. In this research we assess the use of a quantitative methodology that was proposed to find the threshold effects, which are redefined as the acceptable risk level.

3. RESEARCH METHOD

In this section, we introduce the research methodology in which first, to find the threshold values of object-oriented metrics based on the bad smell. Two version (1.0.0 pre1 and 1.0.1) of jfreechart were taken for analysis. First, we collected the CK metrics and badsmell databases of these two versions of jfreechart from Analyst4j tool. The objective is to use the logistic regression to investigate the threshold effects of the CK metrics. Only the significantly associated metrics were considered for finding the threshold values using bad smell at various risk level.

3.1 Software Measurements

We have selected the CK metrics as evidenced by previous empirical studies. The CK metrics are defined as follows:-Coupling between Object (CBO) metric counts the number of classes to which it is coupled Line of Code (LOC) is calculated as the sum of no. of fields, the no. of nodes and the no. of instructions in a given class. Response for Class (RFC) is the count of set of all the methods that can be invoked in response to a message to an object of a class. Weighted Method Complexity (WMC) metric is the sum of all the

Vol. 2 Issue 3, March - 2013

complexities of all the methods in a class. Lack of cohesion of methods (LCOM) measure the dissimilarity of methods in a class. Depth of inheritance (DIT) is the maximum no. of steps from the class node to the root of the tree.

3.2 Bad Smell Measurements

Identify bad smells in code helps to refactor the code. Refactoring of software code is a very tedious problem and applying it manually is yet more difficult. A number of surveys have been done for refactoring and maintainability. There is a need of external attributes to refactor the code for better understandability. Metrics provide solid information regarding object oriented properties. Research results show relationship between structural attributes and external quality metrics. In this paper we find five different bad smell categories in which different bad smells are identified and refractor to ensure maintainability. Table 1 shows the different bad smell categorizations which contain various bad smells in it.

4. ANALYSIS METHODS

The method that we use to perform this analysis is based upon the Logistic regression model. The logistic regression is used to validate the metrics and to calculate the threshold values.

4.1 Univariate Binary Logistic Regression Analysis

Univariate Binary Logistic In the **Analysis** Regression(UBR) significant metrics for predicting bad smell were selected. Analysis was done at the 95 percent confidence level (P-value < 0.05). Univariate Binary Logistic In the Regression (UBR) Analysis significant metrics for predicting bad smell were selected.

Table 1. Bad Smell Categorization

SNo	Bad Smell	Bad Smells			
•	Category				
1.	Blob Class	 Large Objects 			
		 Large Attributes 			
		 Long Methods 			
		 Large Class 			
		• Long Parameter			
	TT 1	List			
2.	Undocumen	• No proper			
	ted Code	Documentation			
		 Comments 			
3.	Using	 Parallel Inheritance 			
	Inheritance	Hierarchies			
		 Feature Envy 			
4.	Procedure	 Switch Statements 			
	oriented	 Alternative classes 			
	Design	with different			
	-	interfaces			
5.	Complex	Duplicate Code			
\$c	Class	• Data Class			

Analysis was done at the 95 percent confidence level(P-value < 0.05).If the metrics has p-value greater than 0.05 then it is neglected, it means that we can't calculate the threshold values for the next step. Table 2. shows the significance levels(p-values) for the Univariate Logistic Regression for the CK metrics of two versions of ifreechart.

Table 2. Univariate Binary Regression Analysis

Metrics	jfreechart(1.0.0 pre1)		jfreechart(1.0.1)		
	В	p- value	В	p-value	
LOC	.009	.000	0.008	.000	
WMC	.034	.000	0.46	.000	
RFC	.025	.000	0.027	.000	
LCOM	N/A	N/A	N/A	N/A	
CBO	.249	.000	0.207	.000	
DIT	1.128	.000	0.703	.000	

It was notice from the UBR analysis that the LOC, WMC, RFC, CBO and DIT metrics are significant predictors of the bad smell between classes at the 95 % confidence level (P < 0.05). That's why, we calculate the threshold values only for these metrics. *Analyst4j* data set does not allow identifying the threshold values for it.

4.2 Threshold Effects Analysis

The threshold values are calculated with the help of Value of Acceptable Risk Level (VARL) using equation (1). Only above mention metrics are calculated with this formula. Table 3 shows the threshold values of selected metrics at different five risk levels (0.5, 0.55, 0.6, 0.65, 0.7) of two different versions of jfreechart.

VARL=
$$p^{-1}(p_0) = 1/\beta (\log (p_0/1-p_0) - \alpha)$$
.
Equation (1)

The Threshold values of selected metrics are given with the VARL formula, in which α and β are the coefficient estimates and the probability p_o is suggested with different five risk levels i.e. ($p_o = 0.5$ to $p_o = 0.7$). Table 3 and Table 4 represent the Threshold values with equation 1 based on bad smell at different five risk levels. Result shows some metrics have effective threshold values for the metrics.

CONCLUSION AND FUTURE WORK

Object-Oriented metrics are more beneficial for the software engineers. Threshold values also provide the meaning to the OO metrics and to identify the various classes at risk. In this work, we find the threshold values of Object-Oriented metrics based on bad smell by using Logistic Regression model. It was concluded that these threshold values also

Table 3. VARL Threshold Values

			VARL	VARL	VARL	VARL	VARL
METRIC	β	α	$(p_o = 0.50)$	$(p_o = 0.55)$	(p _o =0.60)	$(p_o = 0.65)$	(p _o =0.70)
LOC	0.009	-0.003	0	23	45	69	94
WMC	0.034	0.246	-7	-1	5	11	18

СВО	0.249	-0.733	3	4	5	5	6

Table 4. VARL Threshold Values

			VARL	VARL	VARL	VARL	VARL
METRIC	β	α	$(p_o = 0.50)$	$(p_o = 0.55)$	$(p_o = 0.60)$	$(p_o = 0.65)$	(p _o =0.70)
LOC	0.008	-0.025	3	28	54	81	109
WMC	0.047	0.177	-4	1	5	9	14
RFC	0.027	0.018	-1	7	14	22	31
DIT	0.72	-0.153	0	0	1	1	1
СВО	0.208	-0.669	3	4	5	6	7

helps to improve the software quality because classes having more than threshold values will increase the testing efficiency. We found that there are effective threshold values for the selected metrics. At different risk level, we found different effects for the given metrics.
